

A Randomized Trial of Open Source STEM Education Software (SmartGraphs)

Rachel Kay, Andrew Zucker, & Carolyn Staudt

For Presentation as NARST Annual Conference, April 2013

This research was conducted under NSF Grant No. DRL-0918522, awarded to the Concord Consortium (Carolyn Staudt, PI). Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of the National Science Foundation.

The Problem

In recent decades “graphs and other mathematical representations have come to play an increasingly important role in mathematical activities in schools” (Monk, 2003). Graphs are commonly used in science, mathematics and social science classrooms to convey important concepts. In spite of the central role of graphs, students at all ages demonstrate difficulties interpreting graphs (Woolnough, 2000; Zee & McDermott, 1987). As is the case with learning to read or to write, students need to repeatedly explore, create, manipulate, and explain graphs in order to learn how to use them well (Monk, 2003).

SmartGraphs Software

With the clear need for helping students better understand graphs and the concepts represented in graphs (such as slope, velocity, half-life, and global warming), the Concord Consortium developed SmartGraphs under a National Science Foundation grant (DRL-0918522). SmartGraphs activities allow students to interact with graphs, for example by clicking on a point in a graph to answer a question. Visualizations (including animations connected to graphs, and colored highlights on graphs), multiple representations of concepts (such as a table linked to a graph), and other instructional approaches are used that have been demonstrated to show promise in science education (Rangel & Linn, 2007). The features of SmartGraphs can be adapted to create activities across multiple science disciplines and beyond.

SmartGraphs software allows authors to create multi-page lessons or activities that run in a Web browser, without any special installations or downloads. The software is programmed using HTML5. One exception is that some activities make use of motion sensors connected to the computer, and in those cases an invisible Java applet is used, which requires that Java be installed on the student’s computer. Otherwise, SmartGraphs activities do not use Java, Flash or any other plug-in or software besides a modern web browser. This helps assure that these activities are usable in any school with an Internet connection.

The Theory of SmartGraphs

The theory behind SmartGraphs relies on multiple instructional techniques known to help students learn. Therefore, there are several reasons to believe that SmartGraphs will help students understand graphs. As stated previously, SmartGraphs software provides students with multiple ways of looking at data or information. This can be through words, graphs, or tables. When using sensors, the connection is also made through physical motion of an object in front of the sensor.

Another important feature of SmartGraphs is the incorporation of scaffolding within lessons. The scaffolding includes targeted hints that can respond to specific student answers. The scaffolding effectively creates lessons customized to the needs of the students, because only students who need help see scaffolding on any given page. The scaffolding can be in the form of written hints, equations, or visual markers on the graph or table. De Jong (2006) found that this

type of guided inquiry is effective in promoting student learning, specifically stating, “The most effective learning results are found with tools that structure the learning process”. Scaffolding specifically can be important when using technology. “Overall, the literature indicates that scaffolding is critical for students’ ability to regulate their learning and can therefore enhance the learning of complex topics while using hypermedia” (Azvedo et al, 2004, p 348).

Additionally, students are more likely to achieve solid understanding of a topic through practice and reinforcement. The concepts taught in the SmartGraphs activities may be presented in multiple ways throughout an activity. Also, by creating multiple activities designed with overlapping content, students will see the content more than once and be able to apply their previous knowledge. For example, our research relied on four activities related to the motion of objects and a fifth related to acceleration due to gravity. These lessons began with position-time graphs, and using them to understand position, direction, and velocity. From there, activities moved on to more difficult velocity-time graphs, matching them with position-time graphs. Lastly, activities related velocity to acceleration.

Research Study

This two-year study began in August 2011. Teacher volunteers were recruited from Pennsylvania, a state selected because of the common availability of laptops throughout the state as a result of the state’s large-scale Classrooms for the Future program (CFF). All of the research teachers were teaching 8th or 9th grade physical science using one of four common physical science textbooks.

Four SmartGraphs activities were developed focusing on the motion of objects. Motion was selected because it is an important topic covered in all physical science curricula and because learning the topic depends on graphs. Studying the motion of objects also allows for incorporation of a motion sensor. An additional SmartGraphs activity about acceleration due to gravity, a topic that usually follows motion, was developed as well, and made available during the fall of 2011.

Year 1 Research

For the first part of this study (Fall 2011), 35 teachers were randomly assigned to experimental and control conditions. The experimental teachers used four SmartGraphs activities in addition to their usual curriculum, while the control teachers used their usual curriculum alone. All teachers received two days of professional development during August 2011. For the experimental teachers, this time focused on using SmartGraphs. The control teachers were given professional development about activities related to heat and temperature. Teachers in both groups received three motion sensors to bring back to their classes, thereby ensuring that experimental results would be due to use of SmartGraphs, not to availability of sensors. During the first year, nearly 2000 students in 91 classes participated in the study.

The first year of the research study aimed to answer the following research questions:

1. Do students who use SmartGraphs activities learn more than comparison students studying the same topic from the same textbooks, but who do not use SmartGraphs activities?
2. What do teachers using SmartGraphs physical science activities believe about the software, including its match to important learning goals for the motion unit of study?

Year 2 Research

For the second year of the research (Fall 2012), 31 teachers returned to the study. The small number of teachers who were unable to continue from Year 1 to Year 2 cited reasons such as change in curriculum, change in teaching assignments, and change in schools. Of those participating, 2 were not able to complete the research during the fall due to technical issues at their schools, leaving 29 teachers from 26 schools teaching 72 sections of Physical Science to 1403 students. All teachers in the second year used SmartGraphs activities. However, in order to understand more about how SmartGraphs can help students learn about the motion of objects, the activities and treatment conditions were modified to allow different comparisons. The four research groups of teachers for the second year are shown in Table 1, including related research questions as well as comparison data sources.

For Cohort C, the activities were modified so that only one sensor was needed per classroom. This would allow the teacher to use the sensor and a computer projector as a demonstration, while each student could use a computer individually with a student version of the activity that did not use a sensor. During the first year of the research, when teachers could choose their method of delivering activities, we found that most activities with sensors were completed in small groups. It was hypothesized that the benefit to the students in these situations would depend on the size and the dynamics of the group. We also recognized that for many schools having a sufficient number of sensors would be a challenge, but having one sensor would be considerably more affordable. Thus the research for Cohort C attempted to examine the results when those factors were removed, and each student could use an individual computer (without a sensor).

The Smart Graphs slope tool is a specific set of scaffolding steps designed to help students understand and compute slope. The slope tool includes a series of hints and visual cues on the graph and the table, such as arrows indicating “rise” and “run” on the graph. Students would only see the slope scaffolding if they answered an initial slope-related question incorrectly. It was hypothesized that this tool would be valuable to students who had difficulty understanding or calculating slope. In order to test this hypothesis, a set of activities was created that removed the slope tool from the original activities and replaced it with generic text hints. These activities were given to Cohort B in order to test this hypothesis as compared with Cohort D, students who used the regular activities with the slope scaffolding included.

Table 1

Research Groups for Years 1 and 2

Group	Fall 2011	Fall 2012	Research Question 2012	Comparisons
<i>Cohort A</i>	Experimental	Year 1 activities (n = 7 teachers, 20 classes, and 392 students)	Does teacher experience with SmartGraphs affect learning gains?	Results from the same teachers, Year 1
<i>Cohort B</i>	Control	Modified activities without the SmartGraphs slope scaffolding tool (n = 4 teachers, 8 classes, and 177 students)	Does the scaffolding provided by the slope tool lead to different learning gains than more generic scaffolding?	Cohort D
<i>Cohort C</i>	Experimental	Modified activities with whole class (teacher) and individual (student) versions (n = 9 teachers, 21 classes, and 418 students)	Do students learn differently when using SmartGraphs on individual computers compared to students working in small groups?	Cohort A
<i>Cohort D</i>	Control	Year 1 activities (n = 9 teachers, 23 classes, and 416 students)	Do students of the <i>same teachers</i> learn more when using SmartGraphs than without SmartGraphs?	Results from the same teachers in Year 1

The initial goal had been to divide teachers into approximately equal groups, but there were notably fewer teachers in Cohort B. Unfortunately, the small number of teachers who left the study between Years 1 and 2 disproportionately affected Cohort B, but there were still a sufficient number of students to warrant analysis of the results from this group.

Instruments

Two primary instruments were used in the study. One was used to measure student outcomes, and the other was used to understand teachers' experience using SmartGraphs.

Assessment of Student Outcomes

To examine student understanding, identical pre and post-tests were developed. To develop the test, we first developed a set of learning goals for the physical science motion unit, based on analyses of Pennsylvania's science standards and physical science textbooks used in the state. Eighth and ninth grade physical science teachers reviewed these learning goals to confirm that they are, in fact, the targets of instruction. An example of a learning goal used for this project is "Identify constant, positive, negative, and 0 rates of change in position with respect to time from a position-time graph." Then, an expert in item development was hired to construct test items linked to the learning goals. For content validation, physical science teachers examined the items to confirm they matched the learning goals, and that the items were grade appropriate. Tests with these items were piloted, and items that performed best in terms of reliability and validity, and that covered all of the learning goals, were compiled into one test. The test was composed of eight multiple-choice items and twelve open-response items based on a knowledge-integration format (Lee & Liu, 2009).

The test was expected to cover five SmartGraphs activities, but since the fifth activity (on gravity) was not available until the middle of the semester in the fall of 2011 (Year 1 of the research), many teachers had already given the post-test before that activity was available. Therefore, a first pre-post-test analysis examined all 20 test items, while a second analysis examined only the 16 items related to the first four SmartGraphs activities. For the second year of research (fall 2012), two of the twenty items were removed from the test. One multiple-choice item was removed because its content was not adequately covered in the five SmartGraphs activities. One open-response item was removed since it detracted from reliability and was inaccessible to most students, even on the post-test. One of these items was part of the 16 items used to evaluate the first four activities, so analyses looking at only these four activities across years only include 15 items.

Weekly Logs

The other key source of information was teacher logs. After each week in which teachers taught motion, they were instructed to complete a log online that detailed what content was covered, what technology was used, and any special circumstances. In Year 1, nearly 500 teacher logs were completed, each accounting for one week for a particular section during the time teachers taught motion and gravity. In Year 1, the experimental teachers were also asked which SmartGraphs activities they used, how the activities worked in the classroom and how well they matched the physical science curriculum. In Year 2, all groups were asked about their experience with SmartGraphs. Cohort A was also asked how their experience compared with their first year using SmartGraphs, while Cohort C was asked how the particular format with only one sensor worked for that activity.

Results

Results from Year 1 are briefly summarized below. Then Year 2 results are presented.

Year 1 Results

The first year of the study included 1,686 students who took both the pre and post-tests. After eliminating items related to the fifth activity on gravity, results showed improvement for students in both experimental and control groups, but the gain scores were significantly greater for students in the experimental group. However the effect size difference was small (0.13 for the complete test). Results from teacher logs responding to items about the SmartGraphs activities showed that teachers felt the content was appropriate, addressed the class's learning goals, and helped students meet those goals. For 99% of the instances reports on the logs, teachers said they would use that activity again, either as is (63%) or with minor changes (36%). Thus while the difference in learning gains was small between the two groups, the teacher response to the activities was sufficiently positive to warrant further investigation of the strengths of SmartGraphs in Year 2. (Further results from the first year of the study can be found in Kay, Zucker, & Staudt, 2012.)

Year 2 Results

In the second year of the study, there were 1,403 students who completed both the pre- and post-tests. The test was composed of 7 multiple-choice items (worth 1 point each) and 11 open-response items (worth up to 4 points each) for a total of 51 possible points on the test. Because of the structure of the rubric for the open-response items, receiving 4 points on any given item was extremely difficult, therefore, the maximum points scored on the pre-test was 43 with a median of 16, and the maximum points scored on the post-test was 45 with a median of 23. Results of the pre and post-tests by cohort are shown in Table 2. When computing multiple-choice scores, the multiple-choice portions of open-response items were included, so there are a total of 13 multiple-choice items evaluated for this score.

Table 2

Results of Pre and Post-Tests

	Cohort A		Cohort B		Cohort C		Cohort D	
	n = 392		n = 177		n = 418		n = 416	
	Pre	Post	Pre	Post	Pre	Post	Pre	Post
Total Score	13.94	20.77	18.02	25.80	18.33	22.54	15.38	21.12
Multiple-Choice Score	5.68	8.10	6.71	9.27	6.80	8.66	6.02	8.18
Open-Response Score	11.04	16.61	14.54	20.82	14.89	18.00	12.41	16.84

For all question types, students in Cohorts A and D started significantly below students in Cohorts B and C, as measured by analysis of variance (ANOVA). Also on all three measures

(total score, multiple-choice score, and open-response score), students in all cohorts significantly improved from pre-test to post-test.

Table 3 and Figure 1 show the gain scores for each cohort of students. ANOVA showed significant differences between cohorts for all three scores. For all three scores, Cohort C (one sensor for the teacher and individual computers without sensors for the students) always showed significantly lower gains than Cohorts A and B, and significantly lower gains from Cohort D for total score and open-response score. For the total test score gain, Cohort B (no slope tool) showed significantly greater gains than Cohort D, the group that used the slope tool. Both Cohorts A and B showed significantly greater gains than Cohort D for open-response score.

Table 3

Results of Pre and Post-Test: Gain Scores

	Cohort A	Cohort B	Cohort C	Cohort D	<i>All students</i>
	n = 392	n = 177	n = 418	n = 416	n = 1403
Total Score	6.83	7.78	4.21	5.74	5.85
Multiple-Choice Score	2.42	2.56	1.86	2.15	2.19
Open-Response Score	5.57	6.28	3.11	4.43	4.58

Figure 1

Results of Pre and Post-Test: Gain Scores

Also, in the second year of the study 328 logs were completed across all teachers in all cohorts. Each teacher completed a log for each section participating in the research (up to three

sections) starting the first week they taught motion until the week they administered the post-test to that class.

Table 4 shows teacher responses to two questions asked about each activity they completed. In the first column, the amount of agreement with the statement “The activity helped my students meet the learning goals” is shown. As can be seen from the table, the great majority of teachers felt that the activity did meet the learning goals of the class. The last column of Table 4 shows teacher responses to the question “Would you use this activity in your classroom again?” Again, the responses were overwhelmingly positive.

Table 4

Selected Responses from Weekly Logs in Year 2 (2012)

	The activity helped my students meet the learning goals.	Would you use this activity in your classroom again?
	Strongly Agree or Agree	Yes or Yes with minor changes
Cohort A	100% (n=90)	100% (n=91)
Cohort B	95% (n=40)	95% (n=40)
Cohort C	96% (n=81)	99% (n=81)
Cohort D	86% (n=114)	92% (n=115)
TOTAL	94% (n=325)	96% (n=327)

The most positive responses came from Cohorts A and C. You will recall that these two groups of teachers had used the SmartGraphs activities the previous year. The least positive responses came from Cohort D. It should also be recalled that Cohorts B and D used five activities, including the fifth activity (Was Galileo Right?) about acceleration due to gravity. Cohorts A and C did not use the gravity activity so their results would be comparable with what they had completed the previous year. Therefore, it made sense to examine if responses for “Was Galileo Right?”, the fifth activity, were different from the results for all activities taken together. In fact, for this activity, only 73% of the teachers in Cohorts B and D agreed or strongly agreed with the statement “The activity helped my students meet the learning goals.” Also, only 77% of teachers would use this activity in their classroom again, either as is or with minor changes. Therefore, it seems likely that the differences in teachers’ attitudes between the cohorts was a result of use of this fifth activity.

Comparison of Year 1 and 2 Results

Four research questions focus on a comparison of Year 1 and Year 2 data. Findings about each of these questions are discussed below.

Research Question 1: Does teacher experience with SmartGraphs affect learning gains?

To answer the first research question, results from students of Cohort A teachers were compared from Year 1 (2011) to Year 2 (2012). Because many of the teachers in Cohort A were unable to use the fifth activity during the first year, they were instructed to only complete the first four activities in the second year so that results could be compared to Year 1. To answer this research question, the fifteen items unrelated to the fifth activity were compared across years. There were 5 multiple-choice questions and 10 open-response questions, for a possible point total of 45. Across all 15 questions there were 11 multiple-choice items (using the multiple-choice parts of open-response items as part of this score) for 11 possible multiple-choice points. The open-response score was composed of scores from the 10 open-response items, worth a total of 40 points. The mean scores for Cohort A students in the two years are shown in Table 5.

Table 5

Pre and Post-Test Results by Year for Cohort A Students

	2011 (n = 416)		2012 (n = 392)	
	Pre-Test	Post-Test	Pre-Test	Post-Test
Total Score (45)	12.32	18.42	11.34	17.46
Multiple-Choice (11)	4.96	6.24	4.52	6.67
Open-Response (40)	10.34	15.53	9.61	14.72

There was no significant difference between years for total test scores and open-response scores on either the pre-test or post-test. However, there was a significant difference between years for both the multiple-choice pre-test and multiple-choice post-test, with the 2011 students outperforming the 2012 students on the pre-test, but 2012 students outperforming the 2011 students on the post-test. Gain scores (Figure 2) confirm this difference, showing that the gains for total score and open-response score were nearly identical between years, but the difference in gains for multiple-choice scores was significantly different by year ($t = -7.348$, $df = 806$, $p < .0005$), with greater gains in 2012 than in 2011. The multiple-choice score indicates a factual understanding of comments as opposed to the open-response items, which reflect a deeper ability to explain the items. Thus the increase in multiple-choice gains would indicate that students understood more of the concepts taught in SmartGraphs better during the second year.

Figure 2

Pre and Post-Test Gains by Year for Cohort A Students

Weekly logs continued to show satisfaction with the activities from 2011 to 2012, with the ceiling for agreement eliminating the possibility for improvement. For example, in 2011, 100% of Cohort A teachers agreed or strongly agreed with the statement “The activity helped my students meet the learning goals,” and again 100% agreed with the statement in 2012. Similarly, in 2011, 100% of Cohort A teachers said they would use the activity again as is or with minor changes, and in 2012, 100% of teachers still would use the activity again. Teacher comments however supported the idea that experience with the activities was helpful in their implementation of the activities. For example:

I prepped more for the activity this time – I went through all of the key terms, checked for understanding and demonstrated how to do the activity before the students actually did it. When they started it, the process ran smoother.

I am more confident, and know more what to expect to help students.

I found the experience using this activity this year as compared to last year much easier. I was able to troubleshoot issues and felt more prepared.

Overall, while the experience of the teacher only lead to small increases in learning gains, the increase in teacher comfort and confidence was evident and important to the implementation of activities.

Research Question 2: Does the scaffolding provided by the slope tool lead to different learning gains than more generic scaffolding?

In order to specifically assess differences in learning gains by access to the slope tool, lessons were created with the slope tool removed as described previously. Cohort B used these revised activities whereas Cohort D used the activities with the slope tool. As was previously noted, Cohort B students had significantly higher gains than Cohort D students on both the total test score and the open-response test score. This would imply that the use of the slope tool leads to decreased learning gains. In order to examine this further, learning gains for the same 18 items were examined from Year 1 of the study. In Year 1, the gains of Cohort B were significantly greater than the gains of Cohort D in all three categories. However the increase in gains from 2011 to 2012 was less for Cohort B than for Cohort D, indicating that Cohort D may be “catching up.” This difference in gains for the total score is shown in Figure 3. Results for multiple-choice and open-response scores are similar.

Figure 3

Gain Scores of Cohorts B and D by Study Year

Items from the 2012 assessment that specifically included computation of slope were examined further. There were three multiple-choice items and two open-response items. Results for these five items are shown in Table 6. As seen in the table, three of the slope items (3, 6, and 10) do not show significant differences in gains for Cohorts B and D, but two items (2 and 16) do show significant differences. But again, these differences favor Cohort B.

Table 6

Gains on Items Involving Computation of Slope

		Cohort B			Cohort D			
		n = 177			n = 416			
		Pre	Post	Mean Gain	Pre	Post	Mean Gain	Significant difference in gains?
Multiple-Choice	Item 2	0.37	0.78	0.41	0.30	0.60	0.30	t = 2.202, df = 591, p = .028
	Item 3	0.65	0.82	0.17	0.56	0.72	0.16	t = 0.212, df = 591, p = .832
	Item 6	0.40	0.75	0.34	0.36	0.61	0.25	t = 1.561, df = 591, p = .119
Open-Response	Item 10	1.34	1.80	0.46	1.04	1.47	0.44	t = 0.252, df = 591, p = .801
	Item 16	0.82	1.89	1.07	0.70	1.45	0.75	t = 2.925, df = 591, p = .004

That the group without slope scaffolding performed significantly better than the group with the slope tool could be an artifact of the particular teachers in these cohorts, as students of the same teachers in Cohort B also had greater gains than students of Cohort D in the first year of the study when neither group was using SmartGraphs. However, the size of the sample (593 students in 31 classes) suggests that this is an unlikely explanation.

Thus, these results disprove our original hypothesis, that the scaffolding included in the slope tool, providing connections between text, graph, and table, helps students more than generic scaffolding (not graphically tied to the particular graph shown to students).

Research Question 3: Do students learn differently when using SmartGraphs on individual computers compared to students working in small groups?

For this question, students in Cohort A compared to Cohort C students. Both groups used four SmartGraphs activities in Year 1. As described above, the activities for Cohort C were modified into teacher and student versions, with only one sensor required (to use with the teacher version). By contrast, Cohort A teachers could assign the activities however worked best with their classes. The great majority of teachers in Cohort A had students work in small groups, with an average of five sensors per class (i.e., five groups, each with one sensor and one computer).

To examine the data pertaining to this research question, the weekly logs from the three activities which required sensors were compared for Cohort A and Cohort C teachers. In Cohort A, there were 69 instances of sections using one of the three motion sensor activities. In 86% of the cases using these three activities the teachers *strongly agreed*, “the activity helped my students meet the learning goals.” In 97% of the cases teachers reported they would use the activities again “as is” while in 3% of the cases they reported they would use the activities again “with minor changes.”

In Cohort C there were 60 instances of sections using one of the three motion sensor activities. In 52% of the cases using these three activities the teachers *strongly agreed*, “the activity helped my students meet the learning goals.” In 70% of the cases teachers reported they would use the activities again “as is” while in 28% of the cases they would use the activities again “with minor changes.” In the other 2% of cases teachers reported they would not use the activity again.

There was one activity (Describing Velocity) that did not require use of a motion sensor. In Cohort A 78% of the time that teachers used that activity with a section they reported they strongly agreed, “the activity helped my students meet the learning goals,” and 100% of the time they would use it again “as is.” When Cohort C teachers used that activity, 48% of the time they strongly agreed, “the activity helped my students meet the learning goals,” and 48% of the time they reported they would use the activity again “as is.”

Explaining these differences is challenging. It is possible that these teachers’ experiences using only one sensor per class for the first three activities biased their perceptions of the fourth (non-sensor) activity. It is also possible that the teachers differed in their opinions about the value of the activities as early as last year. To test the latter proposition, we used last year’s data set and divided the experimental teachers into the same two cohorts, A and C. Indeed, we find that they did differ in their perceptions of the value of activities in 2011, as shown in Table 7.

Table 7

Opinions of Cohort A and C Teachers About SmartGraphs activities in 2011 and 2012

	SENSOR ACTIVITIES		DESCRIBING VELOCITY	
	Helped students (strongly agree)	Use again as is	Helped students (strongly agree)	Use again as is
Group A 2011	86%	77%	74%	70%
Group A 2012	86%	97%	78%	100%
Group C 2011	60%	64%	64%	52%
Group C 2012	52%	70%	48%	48%

These data tend to show that Cohort A teachers’ second year of experience using the activities in the same manner increased their confidence in the activity, especially their opinion that they would use the activity again “as is.” In contrast, Cohort C teachers, who used the sensor activities in a different way the second year than the first year, did not exhibit growing confidence in using the activities—even the non-sensor activity.

In response to the question, “Was this an effective method to use SmartGraphs activities with your class? Please explain,” there were many comments to the effect that the single sensor

was an effective method. For example, one teacher wrote, “Yes, it went very well with our class discussions and lessons.” Another comment was, “Yes. I think overall the students learned better by completing the activity together [and] then, trying the rest of the lab on their own.”

However there were also indications some teachers were not enthusiastic about using a single sensor in the teacher version of the activity (and no sensors in the student version of the same activity) and teachers provided reasons why. Here are some of the negative comments teachers in Cohort C made:

No. ... I will never do this activity as a full class again. The small group work was so much better in terms of student collaborating and time wise, where you don't have to wait for the slower students to finish answering questions and before you know it the class period is over. I feel that I have wasted so much time this unit waiting.

I actually did not like doing this activity as a whole class. I found it difficult to keep track of what page the students were supposed to be on versus what page the projector was on. I didn't like that not all students were able to take a turn creating a graph with the motion sensor. I also didn't like how the whole class was stuck waiting for a few slower students to finish before we could move on to the next page and the activity does not allow for collaboration among students (students teaching other students).

I prefer having them work in lab groups since the computers don't all move at the same rate sometimes students get behind where we are working.

As seen previously (in Figure 1), gain scores from students in Cohorts A and C were significantly different, with Cohort A showing greater gains than Cohort C. This was true for the complete test as well as when the items related to the fifth activity were removed (because Cohorts A and C did not use the fifth activity). In the first year of the study, gains were also greater for Cohort A students, but the difference was significant only when looking only at items related to the first four activities. Thus the differences between the gains of students in Cohorts A and C may reflect a difference between these two groups of teachers more than a result of the difference in use of the sensors. Thus the effect of presentation mode (one sensor or many sensors per class) likely does not affect learning gains.

In summary, although the evidence is somewhat ambiguous, and not all teachers agreed, it appears that there is greater enthusiasm by teachers for using multiple sensors with small groups of students, rather than a single sensor projected for the whole class to see.

Research Question 4: Do students of the *same teachers* learn more when using SmartGraphs than without SmartGraphs?

While the first year of the study compared learning gains between students taught by teachers with or without SmartGraphs software—a classic experimental trial—one advantage of a two-year study is the ability to compare students of the same teachers teaching without and then, a year later, with the SmartGraphs software. While the students between years have changed, it is expected that there are enough constants between the years, such as school,

population characteristics, curriculum, and teaching style, that a two-year comparison between students of the same teachers should have strong credibility.

In order to make this comparison, the 18 items that were common between the assessments in both years were used to compute scores and gain scores. Results are shown in Table 8 and Figure 4 for students of teachers in Cohort D, who used SmartGraphs in 2012 but not in 2011.

Table 8

Pre and Post-Test Results by Year for Cohort D Students

	2011 (n = 365)		2012 (n = 416)	
	Pre-Test	Post-Test	Pre-Test	Post-Test
Total Score (51)	14.01	18.17	15.38	21.12
Multiple-Choice (13)	5.68	7.30	6.02	8.18
Open-Response (44)	11.14	14.49	12.41	16.84

Figure 4

Gain Scores for Cohort D by Year

In the second year of the study, students of Cohort D teachers had significantly higher pre-test scores (for total score and open-response score), but even with this difference in starting point, the gains were also significantly higher for all three categories (total score: $t = -3.907$, $df = 779$, $p < .0005$; multiple-choice score: $t = 03.257$, $df = 779$, $p = .001$; open-response score: $t = -2.911$, $df = 779$, $p = .004$).

Based on this information one can conclude that use of SmartGraphs leads to greater learning gains than instruction by the same teachers using the same textbooks but without SmartGraphs. Although usually considered small, the effect size differences between years are greater for this two-year comparison than the effect size comparing outcomes for the experimental and control groups in Year 1. Specifically, comparing 2012 and 2011 results for Cohort D, the effect size for the total score gain was $d = 0.28$, for the multiple-choice gain was $d = .23$, and for the open-response gain was 0.31, showing higher student outcomes in 2012 when SmartGraphs was used. In terms of learning gains, an effect size of 0.28 corresponds to moving a student from the 50th percentile (on the total score) to the 61st percentile.

Conclusions

Multiple analyses of data from this two-year randomized experimental study allow us to reach five conclusions. We have a high degree of confidence in these conclusions.

1. Using SmartGraphs activities that focus on the motion of objects as a supplement to normal instructional activities in physical science classes results in statistically significant learning gains for students. This conclusion was reached in Year 1, and then confirmed with a new set of comparisons in Year 2. Replicating the finding makes us more confident that the conclusion is correct, as does the large number of schools, teachers, and students who participated in the research.¹

2. Teachers overwhelmingly reported that the activities helped students achieve learning goals for this unit of study, and that they would use the activities in the future. Once again, the Year 1 finding was replicated in Year 2. For example, on 94% of the weekly logs submitted in Year 2 teachers agreed or strongly agreed that, “the activity helped my students meet the learning goals” (Table 4).

3. Teachers who used SmartGraphs for a second year had greater confidence in their use of the activities. Although this finding is not surprising, it is a reminder that changing instructional practice takes time. Teachers need time to learn and become comfortable with new ways of teaching. Although there was not a greater gain on students’ total test score in Year 2, the score on the multiple-choice portion of the test was statistically higher in 2012 than in 2011, suggesting that teachers’ greater confidence using the activities also had a favorable impact on student learning (Figure 2).

4. The scaffolding tool we developed to help students understand slope apparently did not add value to the activities. This is a surprising finding to the project team because we expected the slope tool would be valuable, or we would not have created it. Yet both an analysis of total test score and an analysis of test items specifically focusing on slope did not show an advantage for students in the cohort using the slope tool, as compared to students receiving

¹ We recognize that this data would best be analyzed using hierarchical linear modeling to account for the clustered nature of classroom data. This analysis will be completed for future results to accompany the results presented here.

generic hints about slope (Table 6). One possible explanation for this finding is that many more students had difficulty calculating the slope of a line on a position-time graph than we expected. In one activity, for example, where the velocity was a whole number (2 meters per second), about 60% of students asked to calculate the slope provided an incorrect answer (which then resulted in them responding to scaffolding questions about slope provided by the slope tool, such as calculating the “rise” and the “run” depicted by arrows on the graph). Evidently many eighth and ninth grade students’ understanding of slope is so weak that a different intervention is needed than the one provided by the SmartGraphs slope tool. Future investigations would be useful in developing features (such as an improved slope tool) and new activities for SmartGraphs.

5. Teachers using motion sensors as part of SmartGraphs prefer having small groups of students use a motion sensor, rather than using a single sensor and a computer projector. We realized that a single sensor per classroom would be less expensive for schools, but were not sure whether it would be as effective. For this reason, we designed an experiment to compare a single-sensor version of these activities with the 2011 version in which students work in small groups, each group using a sensor. This arrangement also required every student to answer questions on his or her computer (rather than possibly watch while other students in a small group used a computer). Teachers apparently did not agree with this arrangement, in part because coordinating the pages of the activity that students were on with the page the teacher was on was hard to do, and in part because they felt that having more students walk in front of the sensor (in the small groups) was more effective for student learning. As a result we will not further disseminate the version of the sensor activities in which teachers use a sensor but students do not.

As noted, in both years teachers felt that SmartGraphs activities were successful for their students. The following are examples of teacher comments on the activities.

It is very good for making them consider different motions with a graph; many of them hadn't considered starting away from the origin.

The students love this one! They get to play around with the motion sensor and experiment with different movements and the learning is so intuitive they don't realize they're learning!

This is one of my favorite activities because it really helps students relate the motion to the graphs of objects moving forward and backward.

Although this two-year study has concluded, work on SmartGraphs continues. Ultimately, the tools and affordances of SmartGraphs may be useful across curricular areas. To that end, an authoring tool has been developed. This tool allows teachers to create and modify SmartGraphs activities to fit within their own curriculum. Further information can be found at <http://smartgraphs.org>.
